Slope Failure is the movement of mass on slope (falls, slides, flows) Landslide: involves an extensive area, mild slope ($<20^\circ$), movement is slow and gradual. Slope Failure: limited area, steep slope, movement is fast (sometimes with no signs) The stability of a slope should be evaluated when slope movement due to additional

analysis uses single value estimates for each variable in the slope stability equations. The variables used for slope stability analysis are the physical characteristics of the soil and the slope geometry. The output of a traditional stability analysis is a single-value deterministic estimate of whether the slope will stand or collapse.

Slope stability analysis should be used to determine whether a proposed slope meets the required safety and performance criteria during design. This type of analysis is also utilized to determine stability conditions of existing natural or constructed slopes and evaluate the influence of proposed remediation methods if required.

CHAPTER 10

Stability analysis was carried out for five dumps of different geometries following two limit equilibrium methods, namely Sarma (Sarma, 1979) and Bishop (Bishop, 1973). The average minimum FOS as found from the two methods are given in Table 1.19. The table shows that dumps of South Balanda, Mudidih, and Mandaman were unstable per the recommended FOS given in Table 1.5.
