The LVDS 7:1 transmit module receives seven bits of parallel data and a parallel clock, TX\_CLK\_in. TX\_CLK\_in is sent to the fabric CCC block, which generates two output clocks: a parallel clock with the same frequency as TX\_CLK\_in, and a serial clock with a frequency 3.5x that of TX\_CLK\_in.

This type of 1:7 interface shown in Figure 1 (5-line interface shown) and requiring clock multiplication is widely used for video processing when passing data from one device to another in consumer devices such as televisions and Blu-ray players. One video channel is typically five LVDS data lines and one LVDS clock line.

2 Low Voltage Differential Signaling 7:1 Low-voltage differential signaling (LVDS) is a high-speed, low-power, general-purpose interface standard. Also known as the ANSI/TIA/EIA-644 standard, LVDS was approved in March 1996. LVDS uses differential signaling with a nominal signal swing of 350 mV differential. The low signal swing

7:1 LVDS LCD in Spartan 6 Is there an app note (or wizard) for generating a 7:1 SerDes for converting 28 bit input to 4 LVDS output? The XAPP486 is a nice example but does not apply to Spartan 6 because of the 3.5x clock. Low-voltage differential signaling, or LVDS, also known as TIA/EIA-644, is a technical standard that specifies electrical characteristics of a differential, serial signaling standard, but it is not a protocol. LVDS operates at low power and can run at very high speeds using inexpensive twisted-pair copper cables. LVDS is a physical layer specification only; many data communication standards ...

Our MLVDS (multipoint LVDS) products are ideal for applications where designers need to transmit at data rates up to 100 Mbps or 200 Mbps to multiple nodes. MLVDS allows a single pair of differential lines to carry this high speed information, saving on connector size and reducing the number of lanes required to fan out this information.
